## EM7000iS Generator AC Receptacle Selection

## Power Circuits

The EM7000iS generator is equipped with two power circuits. The power available to each receptacle depends on the position of the voltage selector switch.
When the voltage selector switch is in the $120 \mathrm{~V} / 240 \mathrm{~V}$ position, the power circuits operate in series, like two separate generators. Each circuit supplies up to 22.9 amps maximum to specific receptacles as shown in the graphic. Neither power circuit can supply power to the other power circuit's receptacles. It is important, therefore, to balance the load on both power circuits.

When the voltage selector switch is in the 120 V ONLY position, the power circuits operate in parallel, sharing the total load connected to receptacles 1,2,3, and terminal 4A of receptacle 4 . Since both power circuits share the total load, there is no need to balance the load.

## Control Panel

The control panel has a voltage selector switch and four receptacles.

Receptacle 1 is a 30A-120V locking receptacle.
Receptacle 2 is the top outlet of a 20A-120V duplex receptacle.
Receptacle 3 is the bottom outlet of a 20A-120V duplex receptacle.
Receptacle 4 is a $30 \mathrm{~A}-120 \mathrm{~V} / 240 \mathrm{~V}$ receptacle and has two powered terminals, 4A and 4B.
When the voltage selector switch is in the $120 \mathrm{~V} / 240 \mathrm{~V}$ position, receptacle 4 supplies up to 22.9 A at 240 volts from the combination of power circuits $A$ and $B$.

When the voltage selector switch is in the 120 V only position, terminal 4A supplies up to 30 amps at 120 volts from power circuits $A$ and $B$; terminal 4B has no power.

## Voltage Selector Switch

Disconnect or turn off all appliances or tools connected to the generator before changing the voltage selector switch position. The generator may be damaged if the switch position is changed with loads connected and operating.

## 120V ONLY Position

When the voltage selector switch is in the 120 V ONLY position, you do not need to spread the load over the receptacles. You must, however, make sure the load on any receptacle does not exceed its available power shown in the table and the total load does not exceed 45.8 amps .

| Receptacle | Available Power | Total Current <br> Available |
| :---: | :---: | :---: |
| 1 | 30 A at 120 V |  |
| 2 | 20 A at 120 V |  |
| 3 | 20 A at 120 V |  |
| 4 A | 30 A at 120 V |  |
| 4 B | None |  |

## 120V/240V Position

When the voltage selector switch is in the $120 \mathrm{~V} / 240 \mathrm{~V}$ position, you must balance the load on both power circuits. Divide the load between the two sets of receptacles shown in the table. Do not exceed the current rating of any receptacle. Balancing is necessary because each set of receptacles is powered by only one power circuit that can produce a maximum of 22.9 amps .

| Set of <br> Receptacles | Total Current <br> Available | Power <br> Circuit |
| :---: | :---: | :---: |
| $2+4 \mathrm{~A}$ | 22.9 A at 120 V | A |
| $1+3+4 \mathrm{~B}$ | 22.9 A at 120 V | B |
| $4 \mathrm{~A}+4 \mathrm{~B}$ | 22.9 A at 240 V | $\mathrm{~A}+\mathrm{B}$ |

## Overloading

The rated power of this generator is 5.5 kVA ; maximum power is 6.5 kVA . Never exceed the maximum power rating of the generator. Power levels between rated and maximum may be used for no more than 30 minutes.
